Calculations of Characteristic X-ray Energies and Wavelengths and the PIXE Spectrum

- Electronic transitions within inner shells of heavier atoms are accompanied by large energy transfers.
- The inner electrons of high Z elements are bound tightly to the atom, since they see essentially the entire nuclear charge.
- First let's make do a small calculation in order to simplify or lives when we calculate the energies of the orbits.

$$E_{n} = -\frac{Z^{2}me^{4}}{2(4\pi\epsilon_{0})^{2}n^{2}\hbar^{2}} = -\left(\frac{me^{4}}{2(4\pi\epsilon_{0})^{2}\hbar^{2}}\right)\frac{Z^{2}}{n^{2}}$$

$$= -\left[\frac{(9.11\times10^{-31}kg)(1.6\times10^{-19}C)^{4}}{32\pi^{2}(8.85\times10^{-12}\frac{C^{2}}{Nm^{2}})^{2}\left(\frac{6.63\times10^{-34}Js}{2\pi}\right)^{2}} \times \frac{1eV}{1.6\times10^{-19}J}\right]\frac{Z^{2}}{n^{2}}$$

• Let's calculate the lowest energy, or longest expected x-ray wavelengths for the element copper.

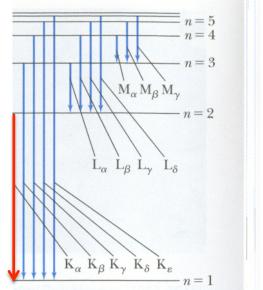

$$_{29}^{64}Cu \longrightarrow 64 \text{ nucleons } \{29 \text{ electrons, } 29 \text{ protons, } 35 \text{ neutrons}\}$$

• The energy of an inner shell electron is given by Z = 29, and n = 1.

$$E_1 = -(13.57eV)\frac{Z^2}{n_{lower}^2} = -(13.57eV)\frac{(29)^2}{(1)^2} = -11412.4eV$$

• The energy of an outer shell electron is given by Z = 29, and n = 2.

$$E_2 = -(13.57eV)\frac{Z^2}{n_{upper}^2} = -(13.57eV)\frac{(29)^2}{(2)^2} = -2853.1eV$$

Thornton, S., & Rex, A., Modern Physics for Scientists and Engineers, 3rd Ed., Thomas Brooks Cole 151(2006).

The UCIBAI

- •This is the transition of an electron from the n = 2 state to the n = 1 state, or an electronic transition from the L-shell to the K-shell.
- This transition is called the K_a transition for copper and the difference in energy between these states is the energy of the emitted x-ray.

The energy of the emitted photon is the difference in energy between the upper state (n = 2) and the lower state (n = 1).

$$\Delta E = E_{upper} - E_{lower} = -2853.1eV - (-11412.4eV) = 8559.3eV$$

This corresponds to a wavelength of

$$\Delta E = \frac{hc}{\Delta \lambda}$$

$$\Delta \lambda = \frac{hc}{\Delta E} = \frac{\left(6.63 \times 10^{-34} Js \times \frac{1eV}{1.6 \times 10^{-19} J}\right) 3 \times 10^{8} \frac{m}{s}}{8559.3 eV} = 1.45 \times 10^{-10} m$$

The actual wavelength (measured in the laboratory) is $1.54x10^{-10}m$.

This is about 70% from the true value!! Hmm...

Comments:

- These wavelengths are calculated based on a hydrogen-like atom using the Bohr model of the atom.
- This means that there is a single electron that transitions.
- The problem with heavy or high Z atoms is that they are rarely single electron atoms.
- So do we live with this or can we fix our results and theory?
- I guess we have to fix the theory since it doesn't give the expected results.

Modifications to the Bohr Theory

- To start, in multi-electron atoms the higher orbital electrons are partially screened from the nucleus.
- In other words they don't see the full nuclear charge of the nucleus.
- The net charge an electron say in the L-shell sees is Ze^- due to the nucleus *minus* e^- due to the one electron in the K-shell (one was ejected.)
- Now, this is only the L to K-shell transitions. Further modifications are needed from M to L-shell transitions, for example.
- Therefore the net charge is $(Z 1)e^{-1}$
- The potential energy is thus

$$V_n = -\frac{(Z-1)e^2}{4\pi\varepsilon_0 r_n}$$

Modifications to the Bohr Theory

• The energy of the orbit is given as

$$E'_{n} = \frac{1}{2} m v_{n}^{2} + V_{n} = \frac{1}{2} m \left(\frac{(Z-1)e^{2}}{4\pi\varepsilon_{0}n\hbar} \right)^{2} - \frac{(Z-1)e^{2}}{4\pi\varepsilon_{0}} \frac{4\pi\varepsilon_{0}n^{2}\hbar^{2}}{m(Z-1)e^{2}}$$

• Doing the math...

$$E_{n} = -\frac{(Z-1)^{2} m e^{4}}{2(4\pi\varepsilon_{0})^{2} n^{2} \hbar^{2}}$$

- •This is the modified Bohr theory to take into account screening of the outer shell electrons by the inner shell electrons.
- How do our calculations look now? Did we do any better?

Modifications to the Bohr Theory and the new X-ray Wavelengths

• Let's recalculate the expected x-ray energy and wavelength for the K_a transition in copper.

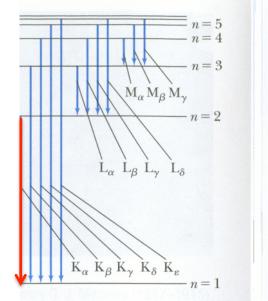

$$_{29}^{64}Cu$$
 \longrightarrow 64 nucleons {29 electrons, 29 protons, 35 neutrons}

• The energy of an inner shell electron is given by Z = 29, and n = 1.

$$E_1 = -(13.57eV)\frac{(Z-1)^2}{n_{lower}^2} = -(13.57eV)\frac{(28)^2}{(1)^2} = -10638.9eV$$

• The energy of an outer shell electron is given by Z = 29, and n = 2.

$$E_2 = -(13.57eV)\frac{(Z-1)^2}{n_{upper}^2} = -(13.57eV)\frac{(28)^2}{(2)^2} = -2659.7eV$$

• This is the transition of an electron from the n=2 state to the n=1 state, or an electronic transition from the L-shell to the K-shell including screening.

Modifications to the Bohr Theory and the new X-ray Wavelengths

The energy of the emitted photon is the difference in energy between the upper state (n = 2) and the lower state (n = 1).

$$\Delta E = E_{upper} - E_{lower} = -2659.7eV - (-10638.9eV) = 7979.2eV$$

This corresponds to a wavelength of

$$\Delta E = \frac{hc}{\Delta \lambda}$$

$$\Delta \lambda = \frac{hc}{\Delta E} = \frac{\left(6.63 \times 10^{-34} Js \times \frac{1eV}{1.6 \times 10^{-19} J}\right) 3 \times 10^{8} \frac{m}{s}}{7979.2eV} = 1.56 \times 10^{-10} m$$

The actual wavelength (measured in the laboratory) is $1.54x10^{-10}m$.

This is about 1.2% from the true value!!

More X-ray Wavelengths...

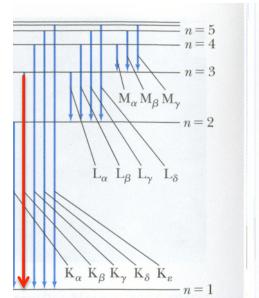

• What is the K_b wavelength for Copper?

$${}^{64}_{29}Cu \longrightarrow {}^{64}$$
 nucleons {29 electrons, 29 protons, 35 neutrons}

- Recalling the energy level diagram for an atom, the K_b transition is from the n = 3 state to the n = 1 state.
- The energies of the upper and lower states are thus

$$E_1 = -(13.57eV)\frac{(Z-1)^2}{n_{lower}^2} = -(13.57eV)\frac{(28)^2}{(1)^2} = -10638.9eV$$

$$E_2 = -(13.57eV)\frac{(Z-1)^2}{n_{upper}^2} = -(13.57eV)\frac{(28)^2}{(3)^2} = -1182.1eV$$

Thornton, S., & Rex, A., Modern Physics for Scientists and Engineers, 3rd Ed., Thomas Brooks Cole 151(2006).

More X-ray Wavelengths...

The energy of the emitted photon is the difference in energy between the upper state (n = 3) and the lower state (n = 1).

$$\Delta E = E_{upper} - E_{lower} = -1182.1eV - (-10638.9eV) = 9456.8eV$$

This corresponds to a wavelength of

$$\Delta E = \frac{hc}{\Delta \lambda}$$

$$\Delta \lambda = \frac{hc}{\Delta E} = \frac{\left(6.63 \times 10^{-34} Js \times \frac{1eV}{1.6 \times 10^{-19} J}\right) 3 \times 10^{8} \frac{m}{s}}{9456 \text{ ReV}} = 1.32 \times 10^{-10} m$$

The actual wavelength (measured in the laboratory) is 1.39x10⁻¹⁰m.

This is about 5.3% from the true value!!

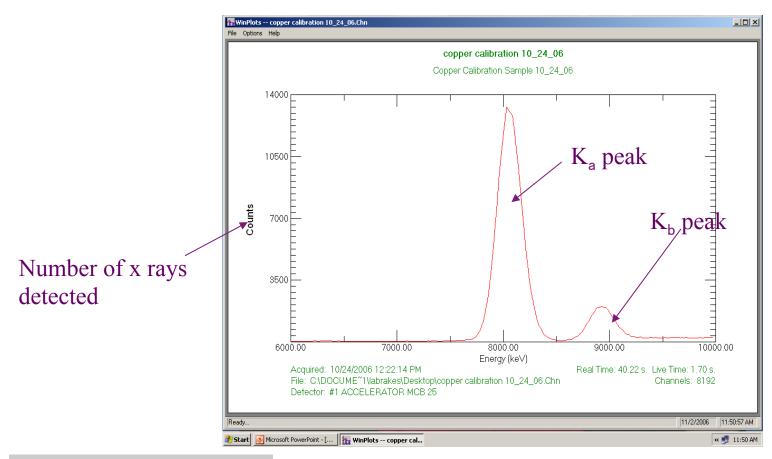

These energies are actually tabulated and in practice look up the element based on the transition energies observed on a calibrated x-ray spectrum

The X-ray Spectrum of Copper

This is a typical *PIXE* plot that shows the x-ray spectrum of copper.

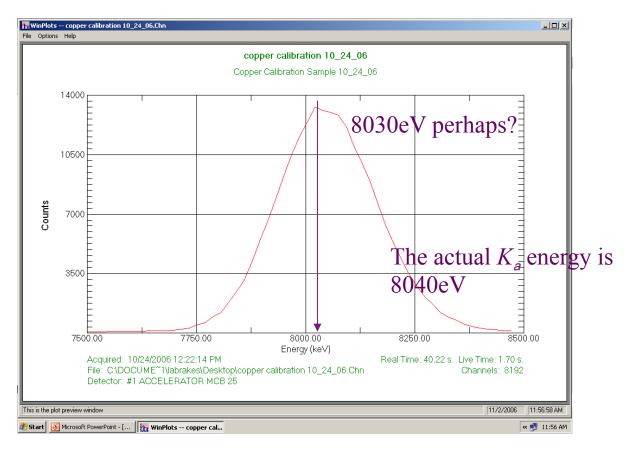

This sample was run on our accelerator and calibrated using a set of standards.

The X-ray Spectrum of Copper

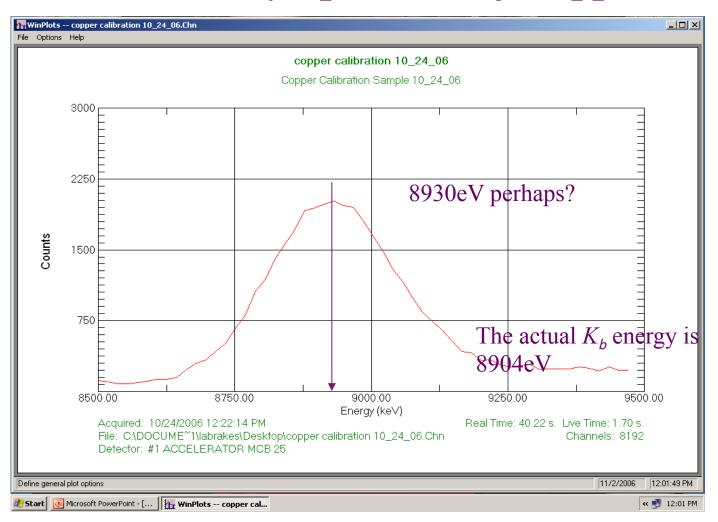

Here we will read off the peak energies and compare those experimentally determined peak energies with the energies of the transitions that we just calculated.

The X-ray Spectrum of Copper

Conclusions

- •So, we can calculate the x-ray transition energies to a fairly high degree of accuracy.
- •There are lots of other effects we haven't looked at, absorption of x-ray, attenuation of x-rays, failure to produce an x-ray (Auger electrons)...
- •Screened Bohr model seems to work well to describe the transitions.
- •X-ray energies for K-series transitions scale with $(Z 1)^2$.
- •L-series x-rays are more complicated how do we describe them?
- •Further, how much of the elements are present?
- •What are the environmental sources of the elements you found?
- •What is the chemical identity of the elements what are the elements bonded too?
