## Exam #3

March 3, 2023

Name \_\_\_\_\_

Please read and follow these instructions carefully:

- Read all problems carefully before attempting to solve them.
- Your work must be legible, and the organization clear.
- You must show all work, including correct vector notation.
- You will not receive full credit for correct answers without adequate explanations.
- You will not receive full credit if incorrect work or explanations are mixed in with correct work. So erase or cross out anything you don't want graded.
- Make explanations complete but brief. Do not write a lot of prose.
- Include diagrams.
- Show what goes into a calculation, not just the final number. For example,  
 $|\vec{p}| \approx m|\vec{v}| = (5\text{kg}) \times (2\frac{\text{m}}{\text{s}}) = 10\frac{\text{kg}\cdot\text{m}}{\text{s}}$
- Give standard SI units with your results unless specifically asked for a certain unit.
- Unless specifically asked to derive a result, you may start with the formulas given on the formula sheet including equations corresponding to the fundamental concepts.
- Go for partial credit. If you cannot do some portion of a problem, invent a symbol and/or value for the quantity you can't calculate (explain that you are doing this), and use it to do the rest of the problem.
- Each free-response part is worth 6 points.

1. Suppose blue light ( $\lambda_{blue} = 450nm$ ) was incident on the equilateral triangular piece of glass ( $n_{glass} = 1.50$ ) as shown below. The glass is surrounded on all sides by air.
  - a. Suppose that you want the blue light to be totally internally reflected at the glass/air interface on the right-hand side of the glass. To do this the light needs to strike the glass/air interface at the critical angle. What is the critical angle for the glass/air interface?

- b. At what angle of incidence  $\theta$  on the left-hand side air/glass interface would the light have to be incident to achieve total internal reflection?

- c. The blue light that emerges through the bottom surface of the equilateral glass block is allowed to be incident on a metal emitter of unknown composition. The blue light ejects electrons from the metal surface and a voltage of  $0.8123V$  is required to stop the ejected electrons from striking the collector. Using this information, what is the work function of the metal emitter?

- d. The blue light incident on the emitter has an intensity  $200 \frac{mW}{cm^2}$ . If the rate of electron production is 95% efficient, what electron current would be measured at the collector if the emitter (and collector) has an area of  $1cm^2$ ?

2. A microscopic creature is swimming in a dish and the creature is too small to see with the naked eye. To see the creature, a system of lenses is used. The first lens (closest to the creature) has a power  $+4.2D$ , while the second lens, located a distance  $L = 1.20m$  from the first lens, has a power  $+8.5D$ .
- a. If the creature, in the dish, is located  $30cm$  to the left of the first lens, where is the image of the creature located with respect to the second lens?
- b. Looking through the two-lens system, the creature was found to be swimming with a speed of  $30\frac{cm}{s}$ . What is the actual speed of the swimming creature in the dish?

- c. What type of image of the creature is produced by the second lens and what is the orientation of the creature's image in the second lens with respect to the creature's orientation in the dish? To earn full credit, be sure to fully explain your answer.

- d. Suppose the creature emits red light with an intensity  $S = 10 \frac{\text{mW}}{\text{cm}^2}$ . What are the maximum values of the electric and magnetic fields in the red light.

3. In a Compton effect experiment, gold x-rays of unknown energy are incident on stationary electrons in an insulating material. The x-rays are detected on a detector located at an angle of  $162^\circ$  measured with respect to the direction of the incident gold x-rays. The scattered electrons in the material are found to have a recoil speed of  $v = 0.232c$ .
- a. What is the kinetic energy (in  $keV$ ) and momentum (in  $\frac{keV}{c}$ ) of the scattered electrons? Express your answer to at least 4 decimal places.
- b. What is the energy (in  $keV$ ) of the incident gold x-rays? Express your answer to at least 4 decimal places.

- c. What is the energy (in  $keV$ ) of the scattered gold x-rays? Express your answer to at least 4 decimal places.

- d. At what angle were the electrons scattered through?
