Physics 111 Quiz #7, March 12, 2021

Please show all work, thoughts and/or reasoning in order to receive partial credit. The quiz is worth 10 points total.

I affirm that I have carried out my academic endeavors with full academic honesty.

____

1. Suppose that you perform a photoelectric effect experiment with gold as the emitter. What is the work function of gold (in eV) if the minimum frequency of incident light needed to eject electrons from the gold surface is $f_{min} = 1.32 \times 10^{15} s^{-1}$?

2. Suppose that you use the same gold emitter, but this time you shine a different color of light onto the metal surface and this particular color causes electrons to be emitted from the gold surface. To stop these electrons from striking the collector, we need to apply a stopping potential difference of $7.7V$. What was the wavelength of the light that was used?

3. Tungsten x-rays ($E = 67.2443keV$) are used in a Compton effect experiment and are observed to scatter from stationary electrons in a block of carbon at an angle of $\phi = 125^0$ with respect to the direction of the incident beam. What is the energy of the scattered x-rays?

4. What is the speed of the recoiling electron expressed as a fraction of the speed of light?
